Beta blockers mechanism of action pdf

Continue

From WebMD "Beta-blockers are a class of drugs used to control symptoms of heart failure that are made worse by certain hormones called catecholamines. The body releases these hormones as part of its response to heart failure. For this and other reasons, beta-blockers have been shown to be effective for treating most people who have heart failure. Beta-blockers may work by slowing the heart rate, which allows the left ventricle (the main pumping chamber of the heart) to fill more completely. Some of these medicines may also have high blood pressure. Bisoprolol, carvedilol, and metoprolol are some of the beta-blockers that have been tested for use in the treatment of heart failure." Beta blockers interfere with the binding to the receptor of epinephrine and other stress hormones. In 1964, James Black[7] synthesized the first clinically significant beta blockers—propranolol and pronethalol; it revolutionized the medical management of angina pectoris[8] and is considered by many to be one of the most important contributions to clinical medicine and pharmacology of the 20th century.[9] For the treatment of primary hypertension, meta-analyses of studies which mostly used atenolol have shown that although beta blockers are more effective than placebo in preventing stroke and total cardiovascular events, they are not as effective as diuretics, medications inhibiting the renin-angiotensin system (e.g., ACE inhibitors), or calcium channel blockers.[10][11][12][13] Medical uses Large differences exist in the pharmacology of agents within the class, thus not all beta blockers are used for all indications listed below. Indications for beta blockers include: Angina pectoris[14][15][16] (contraindicated for Prinzmetal's angina) Atrial fibrillation[17] Cardiac arrhythmia[18][16] Congestive heart failure[19] Essential tremor[20] Glaucoma[16][21] (as eye drops, they decrease intraocular pressure by lowering aqueous humor secretion[22]) Hypertension, [16] although they are generally not preferred as an initial treatment[23] Hyperthyroidism[16] Migraine prophylaxis[24] Mitral valve prolapse[25] Myocardial infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Symptomatic control (tachycardia infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Symptomatic control (tachycardia infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Symptomatic control (tachycardia infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Symptomatic control (tachycardia infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Symptomatic control (tachycardia infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Symptomatic control (tachycardia infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Symptomatic control (tachycardia infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Symptomatic control (tachycardia infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Symptomatic control (tachycardia infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Symptomatic control (tachycardia infarction[26] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Phaeochromocytoma, in conjunction with α-blocker[27] Postural orthostatic tachycardia syndrome[28] Phaeochromocytoma syndrome[28] Phaeochromocytoma syndrome[28] Phaeochromocytoma sy Acute aortic dissection Hypertrophic obstructive cardiomyopathy Long QT syndrome (treatment with propranolol slows progression of aortic dilation and its complications) Prevention of variceal bleeding in portal hypertension Possible mitigation of hyperhidrosis Social and other anxiety disorders Controversially, for reduction of perioperative mortality in non-cardiac surgery, but the best evidence suggests that they increase mortality when used this way[31][32] Congestive heart failure, as they have the potential to worsen the condition due to their effect of decreasing cardiac contractility, studies in the late 1990s showed their efficacy at reducing morbidity and mortality.[33][34][35] Bisoprolol, carvedilol, and sustained-release metoprolol are specifically indicated as adjuncts to standard ACE inhibitor and diuretic therapy in congestive heart failure, although at doses typically much lower than those indicated for other conditions. Beta blockers are only indicated in cases of compensated, stable congestive heart failure; in cases of acute decompensated heart failure; beta blockers will cause a further decrease in ejection fraction, worsening the patient's current symptoms. Beta blockers will cause a further decrease in ejection fraction, worsening the patient's current symptoms. action of importance in congestive heart failure.[36] Beta blockers, in addition to their sympatholytic B1 activity in the heart, influence the renin-angiotensin system at the kidneys. Beta blockers, in addition to their sympatholytic B1 activity in the heart, influence the renin-angiotensin system at the kidneys. capacity of the blood. Heart failure characteristically involves increased catecholamine activity on the heart, which is responsible for several deleterious effects, including increased catecholamine activity on the heart, which is responsible for several deleterious effects. contribute to the low ejection fraction.[37] Beta blockers counter this inappropriately high sympathetic activity, eventually leading to an improved ejection fraction. Trials have shown beta blockers reduce the absolute risk of death by 4.5% over a 13-month period. In addition to reducing the risk of mortality, the numbers of hospital visits and hospitalizations were also reduced in the trials.[38] Therapeutic administration of beta blockers for congestive heart failure ought to begin at very low doses (1/8 of target) with a gradual escalation of the dose. The heart of the patient must adjust to decreasing stimulation by catecholamines and find a new equilibrium at a lower adrenergic drive.[21] Anxiety Officially, beta blockers are not
approved for anxiolytic use by the U.S. Food and Drug Administration.[39] However, many controlled trials in the past 25 years indicate beta blockers are effective in anxiety disorders, though the mechanism of action is not known.[40] The physiological symptoms of the physiological symptoms of the mechanism of action is not known.[40] The physiological symptoms of the physiological symptoms of the mechanism of action is not known.[40] The physiological symptoms of the physiological symptoms of the mechanism of action is not known.[40] The physiological symptoms of the mechanism of action is not known.[40] The physiological symptoms of the physiological symptoms the fight-or-flight response (pounding heart, cold/clammy hands, increased respiration, sweating, etc.) are significantly reduced, thus enabling anxious individuals to concentrate on the task at hand. Musicians, public speakers, actors, and professional dancers have been known to use beta blockers to avoid performance anxiety, stage fright, and tremor during both auditions and public performances. The application to stage fright was first recognized in The Lancet in 1976, and by 1987, a survey conducted by the International Conference of Symphony Orchestra Musicians, representing the 51 largest orchestras in the United States, revealed 27% of its musicians had used beta blockers and 70% obtained them from friends, not physicians.[41] Beta blockers are inexpensive, said to be relatively safe, and on one hand, seem to improve musicians' performances on a technical level, while some, such as Barry Green, the author of "The Inner Game of Music" and Don Greene, a former Olympic diving coach who teaches Juilliard students to overcome their stage fright naturally, say the performances may be perceived as "soulless and inauthentic".[41] Surgery Low certainty evidence indicates that the use of beta blockers around the time of other types of surgery, however, may worsen outcomes. For non-cardiac surgery, the use of beta blockers to prevent adverse effects may reduce the risk of atrial fibrillation and myocardial infarctions (very low certainty evidence), however, there is moderate certainty evidence suggests that beta blockers used perioperatively in non-cardiac surgeries may increase the risk of bradycardia.[43] Performance-enhancing use Because they promote lower heart rates and reduce tremors, beta blockers are banned in some sports by the International Olympic Committee.[45] In the 2008 Summer Olympics, 50-metre pistol silver medalist Aim Jong-su tested positive for propranolol and was stripped of his medals.[46] For similar reasons, beta blockers have also been used by surgeons.[47] Classical musicians have commonly used beta blockers since the 1970s to reduce stage fright.[48] Adverse effects Adverse drug reactions associated with the use of beta blockers include: nausea, diarrhea, bronchospasm, dyspnea, cold extremities, exacerbation of Raynaud's syndrome, bradycardia, hypotension, heart failure, heart block, fatigue, dizziness, alopecia (hair loss), abnormal vision, hallucinations, insomnia, nightmares, sexual dysfunction, erectile dysf barrier, lipophilic beta blockers, such as propranolol and metoprolol, are more likely than other less lipophilic beta blockers to cause sleep disturbances, such as insomnia, vivid dreams and nightmares.[50] Adverse effects associated with β2-adrenergic receptor antagonist activity (bronchospasm, peripheral vasoconstriction, alteration of glucose and lipid metabolism) are less common with \$1-selective (often termed "cardioselective") agents, but receptor selectivity diminishes at higher doses. Beta blockade, especially of the beta-1 receptor at the macula densa, inhibits renin release, thus decreasing the release of aldosterone. This causes hyponatremia and hyperkalemia. Hypoglycemia can occur with beta blockade because \$2-adrenoceptors normally stimulate glycogen breakdown (glycogenolysis) in the liver and pancreatic release of the hormone glucase. B1-blockers have fewer metabolic side effects in diabetic patients; however, blocking \$2-adrenoceptors lowers plasma glucose. B1-blockers have fewer metabolic side effects in diabetic patients; however, blocking \$2-adrenoceptors lowers plasma glucose. B1-blockers have fewer metabolic side effects in diabetic patients; however, blocking \$2-adrenoceptors lowers plasma glucose. B1-blockers have fewer metabolic side effects in diabetic plasma glucose. B1-blockers have fewer metabolic side effects in diabetic plasma glucose. B1-blockers have fewer metabolic side effects in diabetic plasma glucose. B1-blockers have fewer metabolic side effects in diabetic plasma glucose. B1-blockers have fewer metabolic side effects in diabetic plasma glucose. B1-bl the fast heart rate that serves as a warning sign for insulin-induced low blood sugar may be masked, resulting in hypoglycemia unawareness. This is termed beta blockers are to be used cautiously in diabetics.[51] A 2007 study revealed divertics and beta blockers used for hypertension increase a patient's risk of developing diabetes mellitus, while ACE inhibitors and angiotensin II receptor antagonists (angiotensin receptor blockers) actually decrease the risk of diabetes.[52] Clinical guidelines in Great Britain, but not in the United States, call for avoiding diuretics and beta blockers as first-line treatment of hypertension due to the risk of diabetes.[53] Beta blockers must not be used in the treatment of selective alpha-adrenergic agonist overdose. The blockade of only beta receptors increases blood pressure, reduces coronary blood flow, left ventricular function, and cardiac output and tissue perfusion by means of leaving the alpha-adrenergic system stimulation unopposed. [medical citation needed] Beta blockers with lipophilic properties and CNS penetration such as metoprolol and labetalol may be useful for treating CNS and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and beta blockers with lipophilic properties and cardiovascular toxicity from a methamphetamine overdose.[54] The mixed alpha- and cardiovascular toxicity from a by methamphetamine.[55] The phenomenon of "unopposed alpha stimulation" has not been reported with the use of beta blockers for treatment of methamphetamine toxicity.[55] Other appropriate antihypertensive drugs to administer during hypertensive drugs furosemide, and alpha blockers such as phentolamine.[56] Contraindications to reliable sources. Unsourced material may be challenged and removed. required, can be prescribed at the least possible dose to those with mild to moderate respiratory symptoms. [59][60] β2-agonists can somewhat mitigate β-Blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm than the nonselective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm than the nonselective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm than the nonselective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm than the nonselective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm than the nonselective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm than the nonselective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm than the nonselective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-blocker-induced bronchospasm where it exerts greater efficacy on reversing selective β-bloc worsening asthma and/or COPD.[59] Diabetes mellitus Epinephrine signals early warning of the upcoming hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia.[61] Beta blockers' inhibition on epinephrine's effect can somewhat exacerbate hypoglycemia blood glucose level monitoring is necessary for a patient with diabetes mellitus on beta blockers. Hyperthyroidism Abrupt withdrawal can result in a thyroid storm. [57] Bradycardia or AV block Unless a pacemaker is present, beta blockers can severely depress conduction in the AV node, resulting in a reduction of heart rate and cardiac output. One should be very cautious with the use of beta blockers in tachycardic patients with Wolff-Parkinson-White Syndrome, as it can result in life-threatening arrhythmia in certain patients. By slowing the conduction through the AV node, preferential co could lead to a 1:1 conduction with very fast ventricular rate, or worse, ventricular fibrillation. Toxicity Glucagon, used in the treatment of overdose, [62][63] increases the strength of heart contractions, increases intracellular cAMP, and decreases renal vascular resistance. It is, therefore, useful in patients with beta blocker cardiotoxicity.[64][65] Cardiac pacing is usually reserved for patients unresponsive to pharmacological therapy. People experiencing bronchospasm due to the β2 receptor-blocking effects of nonselective beta blockers may be treated with anticholinergic drugs, such as ipratropium, which are safer than beta agonists in patients with cardiovascular disease. Other antidotes for beta blocker poisoning are salbutamol and isoprenaline. β-receptors by epinephrine induces a positive chronotropic and inotropic and inotro kidney causes renin release.[67] Stimulation of β2 receptors induces smooth muscle relaxation,[68] induces tremor in skeletal muscle.[70] Stimulation of β3 receptors induces lipolysis.[71] Beta blockers inhibit these normal epinephrine- and norepinephrine-mediated sympathetic actions,[3] but have minimal effect on resting subjects.[citation needed] That is, they reduce the effect of excitement or physical exertion on heart rate and force of contraction,[72] and breakdown of glycogen. Beta blockers can have a constricting effect on the bronchi of the lungs, possibly worsening or causing asthma symptoms [74] Since $\beta 2$ adrenergic receptors can cause vascular smooth muscle dilation, beta blockers may cause some vasoconstriction. However, this effect tends to be small because the activity of $\beta 2$ receptors is overshadowed by the more dominant vasoconstriction. However, thirdgeneration beta blockers can cause vasodilation through blockade of alpha-adrenergic receptors.[75] Accordingly, nonselective beta blockers is unclear, but may involve reduction in cardiac output (due to negative chronotropic and inotropic effects).[77] It may also be due to reduction in renin release from the kidneys, and a central nervous system effect to reduce sympathetic activity (for those beta blockers that do cross the blood-brain barrier, e.g. propranolol). Antianginal effects result from negative chronotropic and inotropic effects, which decrease cardiac workload and oxygen demand. Negative chronotropic properties of beta blockers are readily titrated to optimal rate control. Beta blockers are readily titrated to optimal rate control in many pathologic states. The antiarrhythmic effects of beta blockers are readily titrated to optimal rate control in many pathologic states. atrioventricular node conduction, and prolonged atrial refractory periods. Sotalol, in particular, has additional antiarrhythmic properties and prolongs action potential duration through potassium channel blockade. with a resultant decrease in blood pressure due to decreased sodium and water retention. Intrinsic sympathomimetic activity Also referred to as intrinsic sympathomimetic effect, this term is used particularly with beta blockers that can show both agonism and antagonism at a given beta receptor, depending on the concentration of the agent (beta blocker) and the concentration of the antagonized agent (usually an endogenous compound, such as norepinephrine). See partial agonist for a more general description. Some beta blockers (e.g. oxprenolol, pindolol, penbutolol, labetalol and acebutolol) exhibit intrinsic sympathomimetic activity (ISA). These agents are capable of exerting low-level agonist activity at the β-adrenergic receptor while simultaneously acting as a receptor site antagonist. These agents, therefore, may be useful in individuals exhibiting excessive bradycardia with sustained beta blocker therapy. Agents with ISA should not be used for patients with any kind of angina as it can aggravate or after myocardial infarctions. They may also be less effective than other beta blockers in the management of angina and tachyarrhythmia. [49] α1-receptor antagonism of both β- and α1-adrenergic receptors, which provides additional arteriolar vasodilating action. [78][79] Examples Dichloroisoprenaline, the first beta blocker Nonselective agents Nonselective beta blockers display both β1 and β2 antagonism.[80] Propranolol[80] Bucindolol (has additional α1-blocking activity)[80] Labetalol (has additional α1-blocking activity)[80] Nadolol[80] Oxprenolol (has intrinsic sympathomimetic activity)[80] Pindolol (has intrinsic sympathomimetic activ beta-blockade of the B1 receptors in the heart will act on cAMP. The function of cAMP as a second messenger in the cardiac cell is that it phosphorylates the LTCC and the ryanodine receptor will inhibit cAMP from phosphorylating, and it will decrease the ionotrophic and chronotropic effect. Note that drugs may be cardioselective, or act on B1 receptors in the heart only, but still have instrinsic sympathomimetic activity. [84] Metoprolo[80] Elipsolo (has intrinsic sympathomimetic activity). [84] Metoprolo [80] Nebivolol[80] Esmolol[85] Nebivolol and Bisoprolol are the most \$1 cardioselective beta blockers.[86] \$2-selective agents SR 59230A[89] \$1 selective agents SR 59230A[89] \$1 sel (ISA) Acebutolol,[90] pindolol,[90] mepindolol,[91] oxprenolol, [83] celiprolol,[84] penbutolol[80] Agents organized by lipid
solubility (lipophilicity: metoprolol, bisoprolol, carvedilol, acebutolol, pindolol,[91] oxprenolol,[82] reprinted by lipid solubility (lipophilicity: metoprolol, labetalol, solubility (lipophilicity) (lipoph blockers): atenolol, nadolol, and sotalol Agents with membrane stabilizing effect[93] Carvedilol, propranolol > labetalol, metoprolol, timolol Indication differences Agents specifically labeled for congestive heart failure[80] Bisoprolol, carvedilol, sustained-release metoprolol Agents specifically labeled for glaucoma Betaxolol,[93] timolol,[93] (preventive treatment before and primary treatment after heart attacks) Agents specifically labeled for migraine prophylaxis[98] Timolol, propranolol is the only agent indicated for the control of tremor, portal hypertension, and esophageal variceal bleeding, and used in conjunction with α-blocker therapy in phaeochromocytoma.[49] Other effects Beta blockers, due to their antagonism at beta-1 adrenergic receptors, inhibit both the synthesis of new melatonin and its secretion by the pineal gland. The neuropsychiatric side effects of some beta blockers (e.g. sleep disruption, insomnia) may be due to this effect. [99] Some pre-clinical and clinical research suggests that some beta blockers may be beneficial for cancer treatment.[100][101] However, other studies do not show a correlation between cancer survival and beta blockers in breast cancer.[104] Beta blockers have also been used for the treatment of schizoid personality disorder.[105] However, there is limited evidence supporting the efficacy of supplemental beta blocker use in addition to antipsychotic drugs for treating schizophrenia.[107] See also Alpha blockers.
